## Abstract

$\text{La}_4\text{Ti}_9\text{O}_{24}$  and  $\text{Bi}_2\text{O}_3$ -substituted  $\text{La}_2\text{O}_3\text{--TiO}_2$  glasses were prepared by aerodynamic levitation technique. The effect of  $\text{Bi}_2\text{O}_3$  substitution on the thermal stability, refractive index and transmittance spectrum of the as-prepared samples were investigated. After  $\text{Bi}_2\text{O}_3$  substitution, the stability of  $\text{La}_2\text{O}_3\text{--TiO}_2\text{--Bi}_2\text{O}_3$  glass decreased, but the Abbe number increased with glass refractive indices above 2.2 in visible region. The high refractive index can be attributed to the large oxygen packing densities and electronic polarizabilities of oxygen ions in the glasses.

**Keywords:**  $\text{La}_2\text{O}_3\text{--TiO}_2$  glass;  $\text{Bi}_2\text{O}_3$  substitution; Aerodynamic levitation; Thermal stability; Optical properties

## 1. Introduction

Oxide glass with high refractive index above 2.0 has great potential for application in small optical devices, such as micro-optical lenses. Traditionally, due to their high polarizability in glasses, heavy metals (such as Pb, Bi, Sb and Te) were added into the glasses to enhance the refractive abilities of the products [1,2], in which  $\text{Bi}_2\text{O}_3$  is one of the most promising of these components. However, glasses containing  $\text{Bi}_2\text{O}_3$  cannot be vitrified by conventional processing methods without network former oxides such as  $\text{SiO}_2$ ,  $\text{B}_2\text{O}_3$ ,  $\text{P}_2\text{O}_5$  and  $\text{GeO}_2$ . On the other hand, as one of the most widely utilized containerless processing methods, aerodynamic levitation technique is ideal for preparing glass without network former oxides due to its ability in suppressing heterogeneous

nucleation and precluding contamination from containers at high temperature.

In literature,  $\text{La}_4\text{Ti}_9\text{O}_{24}$  glass was reported to possess high refractive index comparable to glasses containing heavy-metal oxides [3]. Therefore, in the present study, on the basis of  $\text{La}_4\text{Ti}_9\text{O}_{24}$  glass,  $\text{La}_2\text{O}_3\text{--TiO}_2\text{--Bi}_2\text{O}_3$  glasses were prepared by aerodynamic levitation technique for the first time, and the effect of highly polarizable  $\text{Bi}^{3+}$  ions on  $\text{La}_4\text{Ti}_9\text{O}_{24}$  glass was investigated.

## 2. Materials and methods

Spherical glass samples with different nominal molar compositions ( $30.8\text{LaO}_{3/2}\cdot 69.2\text{TiO}_2$ ,  $25.8\text{LaO}_{3/2}\cdot 69.2\text{TiO}_2\cdot 5\text{BiO}_{3/2}$ , and  $30.8\text{LaO}_{3/2}\cdot 64.2\text{TiO}_2\cdot 5\text{BiO}_{3/2}$ ) were prepared with an aerodynamic levitation furnace. During processing, high-purity (99.99 wt%) powders of  $\text{La}_2\text{O}_3$ ,  $\text{TiO}_2$  and  $\text{Bi}_2\text{O}_3$  were first stoichiometrically mixed and sintered at 1200 °C for 4 h in a Muffle oven. After grinding, the resultant fine composite powders were pressed into small columnar rods. The rods were sintered again at 1200 °C for 4 h. After

Fig. 1. DTA curves of  $25.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  and  $30.8\text{LaO}_{3/2} \cdot 64.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  glasses. The arrows indicate the glass transition temperatures.

sintering, the rods were cut into pieces with a weight of approximately 40 mg and levitated by oxygen gas flow in an aerodynamic levitation furnace. Then, the samples were heated rapidly to the melting temperature by a laser and held there for few seconds. After that, the laser was turned off and the samples were cooled down naturally to room temperature. The volatility of  $\text{Bi}_2\text{O}_3$  during heating was considered and the existence of  $\text{Bi}_2\text{O}_3$  in the as-prepared glasses was confirmed by an x-ray fluorescence spectrometer (PANalytical, Axios<sup>mAX</sup>).

The sample density was measured by a gas pycnometer (Micromeritics Accupyc II 1340). The glass transition temperature  $T_g$  and crystallization onset temperature  $T_x$  of the prepared glasses were measured by differential thermal analysis (DTA) at a heating rate of 10 K/min (Netzsch ATA 449). After polishing, the refractive index of the glasses was evaluated using a SPEC ellipsometer (Genuine Optronics Limited, V-VASE). And their transmittance spectra from 190 to 800 nm were recorded by an optical spectrum analyzer (PERSEE TU-1901).

### 3. Results and discussion

The as-prepared  $25.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  glass was almost transparent and colorless, while  $30.8\text{LaO}_{3/2} \cdot 64.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  glass was transparent but yellow. Fig. 1 shows the DTA curves of  $25.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  and  $30.8\text{LaO}_{3/2} \cdot 64.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  glasses. From this figure, it can be seen that the changes of their specific heats around the glass transition were small and the exothermic peaks were very sharp. Their  $T_g$ ,  $T_x$  and  $\Delta T = T_x - T_g$  values and those of  $30.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2$  sample [4] were compared in Table 1. The results indicate that the thermal stability and glass-forming ability of  $\text{La}_2\text{O}_3$ – $\text{TiO}_2$ – $\text{Bi}_2\text{O}_3$  glasses were somewhat inferior to those of  $30.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2$  glass [5].

The transmittance spectra of all the samples in UV–vis region are displayed in Fig. 2. The apparent transmission presents maximum values of about 68%, 54% and 65% for  $30.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2$ ,  $25.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  and  $30.8\text{LaO}_{3/2} \cdot 64.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  glasses, respectively, because of their high refractive indices. The UV absorption edges of  $\text{La}_2\text{O}_3$ – $\text{TiO}_2$ – $\text{Bi}_2\text{O}_3$  glasses are longer than that of  $30.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2$  glass, implying decreased optical band gaps after  $\text{Bi}_2\text{O}_3$  substitution.

Fig. 3. Refractive index dispersions of  $30.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2$ ,  $25.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  and  $30.8\text{LaO}_{3/2} \cdot 64.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  glasses as a function of wavelength.

$\text{O}_{3/2} \cdot 69.2\text{TiO}_2$  glass, implying decreased optical band gaps after  $\text{Bi}_2\text{O}_3$  substitution.

Fig. 3 illustrates the refractive index dispersions of all the glass samples as a function of wavelength of the applied light for measuring. Although the refractive indices of both  $\text{Bi}_2\text{O}_3$ -substituted glasses were slightly lower than that of  $30.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2$  glass at the visible region, they were still keeping high values above 2.2, implying that the as-prepared  $\text{Bi}_2\text{O}_3$ -substituted glasses might be promising in the application of small optical devices.

According to the single oscillator model from the Drude–Voigt relationship, the refractive index  $n$  is expressed as a function of the wavelength  $\lambda$  by the following formula [2]:

$$\frac{1}{n^2 - 1} = \frac{\pi m c^2}{e^2 N f} \left( \frac{1}{\lambda_0^2} - \frac{1}{\lambda^2} \right) \quad (1)$$

where  $n$  is the refractive index,  $m$  and  $e$  are the mass and charge of an electron, respectively,  $c$  is the velocity of light,  $N$  is the number of molecules in unit volume,  $f$  is the average oscillator strength, and  $\lambda_0$  is the inherent absorption wavelength.  $N$  is calculated from the formula  $N = \rho N_A / M$ , where  $N_A$  is Avogadro's number,  $\rho$  is the sample density, and  $M$  is the molecular weight determined from the glass composition. The values of  $f$  and  $\lambda_0$  used in this model are their averages from oscillators such as bridging oxygen, non-bridging oxygen and cations. Based on this model, the plot of  $1/(n^2 - 1)$  vs  $1/\lambda^2$  is expected to be a straight line with a slope of  $\pi m c^2 / (e^2 N f)$  and a y-axis intercept of  $\pi m c^2 / (e^2 N f \lambda_0^2)$ . The values of  $f$  and  $\lambda_0$  are determined from this linear relationship. According to the refractive index dispersion, the Abbe number was estimated for each sample by the formula  $\nu_d = (n_d - 1) / (n_F - n_c)$ , where  $n_d$ ,  $n_F$  and  $n_c$  are the refractive indices of the glasses at 589, 486 and 656 nm, respectively. Part of the corresponding parameters applied in the calculation are listed in Table 2. Although the spectroscopic ellipsometer may be not accurate enough to estimate the Abbe number of glasses precisely, the substitution of  $\text{Bi}_2\text{O}_3$  for both  $\text{LaO}_{3/2}$  and  $\text{TiO}_2$  does increase

the Abbe number of the prepared glasses while keeping the refractive index high.

The dominant factors affecting the refractive index of oxide glasses are oxygen packing density and the electronic polarizability of ions [6–9]. Considering the number of oxygen ions in oxide glass, and relatively larger electronic polarizability of oxygen ions compared to that of cations, this study focuses on the oxygen packing density and electronic polarizability of oxygen ions  $\alpha_O$ . The partial molar volumes of oxygen  $V_O$  and oxygen packing densities of all the prepared glasses in this study were calculated by the same method as proposed by Inoue et al. [9], where the ionic radii of six-coordinated  $\text{La}^{3+}$ ,  $\text{Ti}^{4+}$  and  $\text{Bi}^{3+}$  were 1.06, 0.605, and 1.02 Å, respectively, according to Shannon's ionic radii [10]. The calculated results are presented in Table 3, revealing that when a part of  $\text{LaO}_{3/2}$  or  $\text{TiO}_2$  was substituted by  $\text{BiO}_{3/2}$ , the oxygen packing density decreased, which is supported by the correlation between the oxygen packing density and radius of the cations.

The electronic polarizability of an ion can be estimated using refractive index and sample density by Lorentz–Lorenz equation:

$$\frac{n^2 - 1}{n^2 + 2} \frac{M}{\rho} = \frac{n^2 - 1}{n^2 + 2} V_m = R_m = \frac{4\pi}{3} \sum_i N_i \alpha_i \quad (2)$$

where  $\rho$  is the density of the glass,  $M$  is the molecular weight of the composition,  $V_m$  is the molar volume,  $N_i$  is the number of ion  $i$ , and  $\alpha_i$  is the electronic polarizability of ion  $i$  in the composition. The electronic polarizability of an oxygen ion  $\alpha_O$  can be obtained from the molar refractivity  $R_m$  and electronic polarizabilities of the cations [6–8]. The calculated values of  $\alpha_O$  and  $V_m$  for  $30.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2$ ,  $25.8\text{LaO}_{3/2} \cdot 69.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  and  $30.8\text{LaO}_{3/2} \cdot 64.2\text{TiO}_2 \cdot 5\text{BiO}_{3/2}$  glasses are all listed in Table 4.

The values of  $\alpha_O$  and  $V_m$  increased when both  $\text{LaO}_{3/2}$  and  $\text{TiO}_2$  were substituted by  $\text{BiO}_{3/2}$ . This can be explained qualitatively using the values of  $V_m$  and  $\alpha_O$  of single component crystals according to Dimitrov and Sakka [8]. The values of  $V_m$  and  $\alpha_O$  for  $\text{La}_2\text{O}_3$  [9],  $\text{TiO}_2$  [9] and  $\text{Bi}_2\text{O}_3$  are listed in Table 4, in which the values of  $\text{Bi}_2\text{O}_3$  were calculated using density (8.55 g/cm<sup>3</sup> [8]), refractive index (2.572 at 589 nm [11]) and Eq. (5) proposed by Vesselin Dimitrov and Sumio Sakka in Ref. [8]. The increases in  $V_m$  and  $\alpha_O$  of  $\text{Bi}_2\text{O}_3$ -substituted glasses were caused by the larger  $V_m$  and  $\alpha_O$  values of  $\text{Bi}_2\text{O}_3$  rather than that of the original  $\text{La}_2\text{O}_3$  or  $\text{TiO}_2$ .

Glasses with higher refractive indices are accompanied by higher wavelength dispersion. Low wavelength dispersion glasses require small  $\alpha_O$  and  $\lambda_0$ . However, refractive index tends to decrease with decreasing  $\alpha_O$ . As shown in Eq. (2), the refractive index is determined by not only  $\alpha_O$  but  $V_m$  as well.

|------------------------------|--------------------------------------------------|------------------------------------------------------------------------|------------------------------------------------------------------------|--------------------------------|------------------|--------------------------------|
| $\alpha_O$ (Å <sup>3</sup> ) | 2.45                                             | 2.50                                                                   | 2.66                                                                   | 2.52                           | 2.58             | 3.69                           |
| $V_m$ (cm <sup>3</sup> /mol) | 21.2                                             | 21.6                                                                   | 22.8                                                                   | 52.8                           | 20.8             | 54.5                           |

Therefore, by adding component with apposite values of  $V_m$ ,  $\alpha_O$  and  $\lambda_0$ , glasses with higher refractive index and larger Abbe number can be obtained using aerodynamic levitation technique.

#### 4. Conclusions

$a\text{LaO}_{3/2}-b\text{TiO}_2-c\text{BiO}_{3/2}$  glasses were fabricated by aerodynamic levitation technique. Their thermal stabilities, densities and optical properties were investigated. The oxygen packing densities, electronic polarizabilities of the ions, and inherent absorption wavelengths were estimated from the sample densities and refractive indices. The high refractive index stems from high packing density and high electronic polarizability of oxygen ions in the glasses. The substitution of  $\text{BiO}_{3/2}$  for  $\text{LaO}_{3/2}$  or especially for  $\text{TiO}_2$  was very effective in increasing the Abbe number by keeping the refractive index high. These results are helpful in glass composition design for optical applications in the visible region.
